A Study of Branching Phenomena in the Nonautonomous Piecewise Linear Dissipative Systems with Unsymmetrical Restoring Force in the Case of the External Force with a Sum of Several Harmonics

Once this is understood, the numerical analysis follows from the periodicity conditions and its appropriateness will be clarified.

2. Periodicity Conditions

In this section the system with restoring force (see Fig. 1) expressed in equation (1) will be considered.

$$\ddot{x}+2\alpha\dot{x}+f(x)=e(t) \tag{1}$$

$$f(x)=\begin{cases} l^2x-K^2x_0 & (x\geq x_0) \\ k^2x & (x\leq x_0) \end{cases} \tag{2}$$

where $l^2=k^2+K^2$ ($\cdot$denotes derivative with respect to time t). And we assume the external force $e(t)$ and initial conditions as follows:

$$\left.\begin{array}{l} e(t)=\sum\limits_{i=1}^{m} E_i \cos i\omega t \\[2mm] e(t)=e\left(t+\dfrac{2\pi}{\omega}\right) \end{array}\right\} \tag{3}$$

$$\left.\begin{array}{l} x(0)=M \\ \dot{x}(0)=N \end{array}\right\} \tag{4}$$

In this paper the periodic solutions are classified according to the number of times the solution reaches the corner point during the period. For 2n times the solution is designated as $_nA$ type solution.

Here we derive the periodicity conditions for $_1A$ type harmonic solution in case $M>x_0$ (see Fig. 2) because we shall treat the bifurcation phenomena from $_1A$ type harmonic solution.   From Fig. 2 we have following equations.

$$\left.\begin{array}{l} x_1(t_1)=x_0 \\ x_2(t_2)=x_0 \\ x_3(T)=M \\ \dot{x}_3(T)=N \end{array}\right\} \tag{5}$$

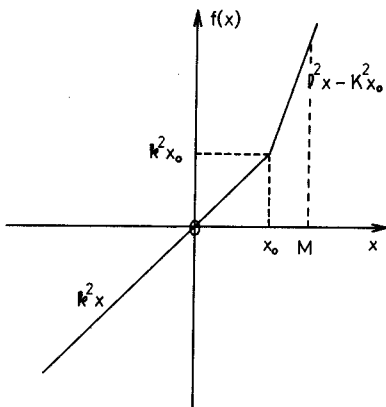

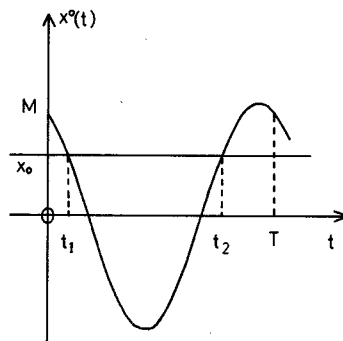

Fig. 1   Restoring force characteristics.

Fig. 2   Periodic solution of type $_1A$

where $x_i(t)$ means the solution for the interval $t_{i-1} \leq t \leq t_i$ ($i=1$, 2, 3, and $t_0=0$, $t_3=T=2\pi/\omega$) and the solution $x_i(t)$ which reaches the corner point x_0 at $t=t_i$ ($i=1$, 2) is connecting the solution $x_{i+1}(t)$ smoothly at every corner point.

Given the system, that is, for given l, k, K, and x_0, equations (5) are the periodicity conditions for obtaining $_1A$ type harmonic solution and mean the relation among the variables: initial value M and N, loss factor α, transition time t_1, t_2, basic frequency ω of the external force, and amplitude E_i ($i=1$, 2, ..., m) of external force. Then if M, N, α, and E_i ($i=1$, 2, ..., $j-1$, $j+1$, ..., m) are known, the remaining elements are obtained, that is to say, ω, E_j, t_1, and t_2 which lead to periodic solution will be found. We assume that the amplitude E_i ($i=1$, 2, ..., $j-1$, $j+1$, ..., m) of the external force is held constant, while the amplitude $E_j(j \neq i)$ is slowly varied and the relations among M, N, and E_j of the periodic solutions mentioned above are observed in what follows.

Finally, we write down the concrete solutions of equations (5) under the conditions (4). In the following solutions, we set

$$\omega_i = i\omega \quad \omega_{01} = \sqrt{l^2 - \alpha^2} \quad \text{and} \quad \omega_{02} = \sqrt{k^2 - \alpha^2} \tag{6}$$

Thus,

$$x_1(t_1) = e^{-\alpha t_1}(A_1 \cos \omega_{01}t_1 + B_1 \sin \omega_{01}t_1) + \sum_{i=1}^{m} \frac{E_i}{(l^2 - \omega_i^2)^2 + 4\alpha^2\omega_i^2} \Big\{$$

$$(l^2 - \omega_i^2) \cos \omega_i t_1 + 2\alpha\omega_i \sin \omega_i t_1 \Big\} + \frac{K^2}{l^2}x_0 = x_0 \tag{7}$$

where

$$A_1 = M - \sum_{i=1}^{m} \frac{E_i(l^2 - \omega_i^2)}{(l^2 - \omega_i^2)^2 + 4\alpha^2\omega_i^2} - \frac{K^2}{l^2}x_0$$

$$B_1 = \frac{1}{\omega_{01}}\Big\{\alpha M + N - \sum_{i=1}^{m} \frac{\alpha E_i(l^2 + \omega_i^2)}{(l^2 - \omega_i^2)^2 + 4\alpha\omega_i^2} - \frac{\alpha K^2}{l^2}x_0\Big\} \tag{8}$$

$$x_2(t_2) = e^{-\alpha(t_2-t_1)}\Big\{(x_0 - p_1)\cos\omega_{02}(t_2-t_1) + \frac{y_1 - q_1 + \alpha(x_0 - p_1)}{\omega_{02}}\sin\omega_{02}(t_2-t_1)\Big\}$$

$$+ \sum_{i=1}^{m} \frac{E_i}{(k^2 - \omega_i^2)^2 + 4\alpha^2\omega_i^2}\{(k^2 - \omega_i^2)\cos\omega_i t_2 + 2\alpha\omega_i \sin \omega_i t_2\}$$

$$= x_0 \tag{9}$$

where

$$p_1 = \sum_{i=1}^{m} \frac{E_i}{(k^2 - \omega_i^2)^2 + 4\alpha^2\omega_i^2}\{(k^2 - \omega_i^2)\cos\omega_i t_1 + 2\alpha\omega_i \sin \omega_i t_1\}$$

$$q_2 = \sum_{i=1}^{m} \frac{\omega_i E_i}{(k^2 - \omega_i^2)^2 + 4\alpha^2\omega_i^2}\{-(k^2 - \omega_i^2)\sin\omega_i t_1 + 2\alpha\omega_i \cos \omega_i t_1\} \tag{10}$$

$$y_1 = e^{-\alpha t_1}\{(-\alpha A_1 + \omega_{01}B_1)\cos\omega_{01}t_1 - (\omega_{01}A_1 + \alpha B_1)\sin\omega_{01}t_1\}$$

$$- \sum_{i=1}^{m} \frac{\omega_i E_i}{(l^2 - \omega_i^2)^2 + 4\alpha^2\omega_i^2}\{(l^2 - \omega_i^2)\sin\omega_i t_1 - 2\alpha\omega_i \cos \omega_i t_1\} \tag{11}$$

$$y_2 = \dot{x}_2(t_2)$$

$$= e^{-\alpha(t_2-t_1)} \left\{ (y_1-q_1) \cos \omega_{02}(t_2-t_1) - \frac{\alpha(y_1-q_1)+k^2(x_0-p_1)}{\omega_{02}} \sin \omega_{02}(t_2-t_1) \right\}$$

$$- \sum_{i=1}^{m} \frac{\omega_i E_i}{(k^2-\omega_i{}^2)^2+4\alpha^2\omega_i{}^2} \{(k^2-\omega_i{}^2) \sin \omega_i t_2 - 2\alpha\omega_i \cos \omega_i t_2\} \tag{12}$$

$$x_3(T) = e^{-\alpha(T-t_2)} \left\{ (x_0-p_2) \cos \omega_{01}(T-t_2) + \frac{y_2-q_2+\alpha(x_0-p_2)}{\omega_{01}} \sin \omega_{01}(T-t_2) \right\}$$

$$+ \sum_{i=1}^{m} \frac{E_i}{(l^2-\omega_i{}^2)^2+4\alpha^2\omega_i{}^2} \{(l^2-\omega_i{}^2) \cos \omega_i T + 2\alpha\omega_i \sin \omega_i T\}$$

$$+ \frac{K^2}{l^2} x_0 = M \tag{13}$$

$$\dot{x}_3(T) = e^{-\alpha(T-t_2)} \left\{ (y_2-q_2) \cos \omega_{01}(T-t_2) - \frac{\alpha(y_2-q_2)+l^2(x_0-p_2)}{\omega_{01}} \sin \omega_{01}(T-t_2) \right\}$$

$$- \sum_{i=1}^{m} \frac{\omega_i E_i}{(l^2-\omega_i{}^2)^2+4\alpha^2\omega_i{}^2} \{(l^2-\omega_i{}^2) \sin \omega_i T - 2\alpha\omega_i \cos \omega_i T\}$$

$$= N \tag{14}$$

where

$$p_2 = \sum_{i=1}^{m} \frac{E_i}{(l^2-\omega_i{}^2)^2+4\alpha^2\omega_i{}^2} \{(l^2-\omega_i{}^2) \cos \omega_i t_2 + 2\alpha\omega_i \sin \omega_i t_2\}$$

$$\left. + \frac{K^2}{l^2} x_0 \right\} \tag{15}$$

$$q_2 = \sum_{i=1}^{m} \frac{-\omega_i E_i}{(l^2-\omega_i{}^2)^2+4\alpha^2\omega_i{}^2} \{(l^2-\omega_i{}^2) \sin \omega_i t_2 - 2\alpha\omega_i \cos \omega_i t_2\}$$

3. Stability

The problem of the infinitesimal stability of the periodic solutions of our nonlinear systems always leads to the equation of Hill's type. The Hill's type equation in these cases is a variational equation characterizing small variations from the given periodic motion whose stability is to be investigated.

A given periodic motion is stable if all solutions of the variational equation associated it are bounded for all positive values of t and unstable if the variational

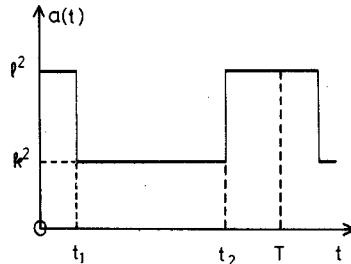

Fig. 3   Coefficient $a(t)$ of periodic solution type $_1$A

equation has an unbounded solution.

Let the $_1A$ type fundamental solution obtained from the periodicity conditions given in section 2 be denoted by $x^0(t)$. The stability of $x^0(t)$ can be determined by the first variational equation of the solution of equation (1). Let the variation be y. The first variational equation is given by

$$\ddot{y}+2\alpha\dot{y}+a(t)y=0 \tag{16}$$

where

$$a(t)\equiv\frac{\partial f}{\partial x}\bigg|x=x^0(t) \tag{17}$$

Also, $a(t)$ is understood to have the following properties:

$$\left.\begin{aligned} a(t)&=a(t+T)\\ a(t)&=\begin{cases}l^2 & (x^0(t)>x_0)\\ k^2 & (x^0(t)<x_0)\end{cases} \end{aligned}\right\} \tag{18}$$

Let the independent solutions of equation (16) be denoted by $\varphi(t)$ and $\psi(t)$ where $\varphi(0)=\dot{\psi}(0)=1$, $\dot{\varphi}(0)=\psi(0)=0$.

Let the two characteristic roots of equation (16) be ρ_1 and ρ_2. Then

$$\left.\begin{aligned} \rho_1\rho_2&=e^{-2\alpha T},\\ \rho_1+\rho_2&=\varphi(T)+\dot{\psi}(T) \end{aligned}\right\} \tag{19}$$

From equations (19) it is clear that the conditions for the stable and unstable region boundary are followed:

$$\text{(i)}\quad \varphi(T)+\dot{\psi}(T)=-1-e^{-2\alpha T} \tag{20}$$

$$\text{(ii)}\quad \varphi(T)+\dot{\psi}(T)=1+e^{-2\alpha T} \tag{21}$$

Equations (20) and (21) become complicated in comparison with those of no damping case.

Finally, we give the concrete form of equations (20) and (21) in terms of α, t_1, t_2, and ω when the periodic solution is the fundamental solution type $_1A$ as shown in Fig. 2 (or Fig. 3).

$$\varphi(T)+\dot{\psi}(T)=e^{-\alpha T}\Big\{2\cos\omega_{02}(t_2-t_1)\cos\omega_{01}(T-(t_2-t_1))$$

$$-\left(\frac{\omega_{02}}{\omega_{01}}+\frac{\omega_{01}}{\omega_{02}}\right)\sin\omega_{02}(t_2-t_1)\sin\omega_{01}(T-(t_2-t_1))\Big\} \tag{22}$$

4. Branching Phenomena

The essential aim of this section is the identification of the branching behavior near bifurcation point of equation (1). In the neighborhood of the $_1A$ type harmonic solution obtained by satisfying the initial conditions (4) of equation (1) in section 2, there exist two situations for the periodic solutions of the variational equation as shown in section 3. Each of the two situations presents a different phenomena. Therefore each is investigated individually.

The solution of equation (1) with $x=M$ and $\dot{x}=N$ at $t=0$ is written by $x(t; M, N, E_j)$ and the functions F and G are defined as follows:

$$
\left.
\begin{aligned}
F(M, N, E_j) &\equiv x(nT; M, N, E_j) - x(0; M, N, E_j) \\
G(M, N, E_j) &\equiv \dot{x}(nT; M, N, E_j) - \dot{x}(0; M, N, E_j)
\end{aligned}
\right\} \quad (23)
$$

where $n=1$ and 2.

It is now clear that solution $x(t; M, N, E_j)$ has a period nT if and only if

$$
F(M, N, E_j) = G(M, N, E_j) = 0 \tag{24}
$$

The point of the (M, N, E_j) space satisfying $F=G=0$ are in general located on a curve and its differential equation are as follows:

$$
\frac{dM}{\begin{vmatrix} F_N & F_{E_j} \\ G_N & G_{E_j} \end{vmatrix}} = \frac{dN}{\begin{vmatrix} F_{E_j} & F_M \\ G_{E_j} & G_M \end{vmatrix}} = \frac{dE_j}{\begin{vmatrix} F_M & F_N \\ G_M & G_N \end{vmatrix}} \tag{25}
$$

where F_M, G_M etc. denote the partial derivatives of the functions F and G with respect to M, N, and E_j. Any point (M, N, E_j) for which denominators of equation (25) vanish simultaneously is called a singular point with respect to equation (25). A point (M, N, E_j) for which denominators do not vanish simultaneously is called an ordinary point.

4.1   Situation (I) $\rho = -1$ (n=2)

When the equation (20) is satisfied, let the point satisfying equations (5) be denoted by (M_0, N_0, E_{j0}) and then we have following results.

$$
F(M_0, N_0, E_{j0}) = G(M_0, N_0, E_{j0}) = 0 \tag{26}
$$

$$
\left.
\begin{aligned}
F_M(M_0, N_0, E_{j0}) &= \varphi(2T) - 1 \\
F_N(M_0, N_0, E_{j0}) &= \psi(2T) \\
F_{E_j}(M_0, N_0, E_{j0}) &= x_{E_j}(2T)
\end{aligned}
\right\} \quad (27)
$$

$$
\left.
\begin{aligned}
G_M(M_0, N_0, E_{j0}) &= \dot{\varphi}(2T) \\
G_N(M_0, N_0, E_{j0}) &= \dot{\psi}(2T) - 1 \\
G_{E_j}(M_0, N_0, E_{j0}) &= \dot{x}_{E_j}(2T)
\end{aligned}
\right\} \quad (28)
$$

where $\varphi(t)$ and $\psi(t)$ are solutions of equation (16), $x_{E_j}(t)$ is the partial derivatives of $x(t; M, N, E_j)$ with respect to E_j and is the evaluation at the point (M_0, N_0, E_{j0}), which is the solution of equation (29).

$$
\left.
\begin{aligned}
\ddot{y} + 2\alpha\dot{y} + a(t)y &= \cos j\omega t \\
y(0) = \dot{y}(0) &= 0
\end{aligned}
\right\} \quad (29)
$$

Then,

$$
\left.
\begin{aligned}
x_{E_j}(t) &= \int_0^t e^{2\alpha\tau}(\varphi(\tau)\psi(t) - \psi(\tau)\varphi(t)) \cos j\omega\tau \, d\tau \\
\dot{x}_{E_j}(t) &= \int_0^t e^{2\alpha\tau}(\varphi(\tau)\dot{\psi}(t) - \psi(\tau)\dot{\varphi}(t)) \cos j\omega\tau \, d\tau
\end{aligned}
\right\} \quad (30)
$$

In this case we may assume the next relations

$$F_M \cdot F_N \cdot F_{E_j} \neq 0 \qquad G_M \cdot G_N \cdot G_{E_j} \neq 0 \tag{31}$$

Here we may evaluate the denominators of equation (25) at the point (M_0, N_0, E_{j0}), using the relationships

$$\varphi(T) + \dot{\psi}(T) = -1 - e^{-2\alpha T} \qquad \varphi(t)\dot{\psi}(t) - \dot{\varphi}(t)\psi(t) = e^{-2\alpha t}$$

$$\varphi(t+T) = \varphi(T)\varphi(t) + \dot{\varphi}(T)\psi(t) \quad \text{and}$$

$$\psi(t+T) = \psi(T)\varphi(t) + \dot{\psi}(T)\psi(t)$$

Omitting the somewhat long calculations, we write down only the results.

$$\left. \begin{array}{l} F_N \cdot G_{E_j} - F_{E_j} \cdot G_N = 0 \\[4pt] F_{E_j} \cdot G_M - F_N \cdot G_{E_j} = 0 \\[4pt] F_M \cdot G_N - F_N \cdot G_M = 0 \end{array} \right\} \tag{32}$$

These indicate that the point (M_0, N_0, E_{j0}) is a geometric singularity of the locus $F = G = 0$.

4.1.1 M-E_j Plane Analysis

We investigate the two-dimensional sections of the three dimensional space (M, N, E_j) which are (M, E_j), (N, E_j), and (M, N). Analysis of branching at an endpoint of an unstable arc of the curve $F = G = 0$ involves the computations of several partial derivatives of the function $F(M, N, E_j)$ and $G(M, N, E_j)$ at the point. Since these computations are long and tedious, we shall omit most of them in what follows. In the analysis of $(M$-$E_j)$ plane, some details will be given to illustrate the procedure. Since $G_N \neq 0$, the equation $G(M, N, E_j) = 0$ can be solved for N as a function of M and E_j near (M_0, E_{j0}). If the result is $N = H(M, E_j)$, we define the function $J(M, E_j)$ by

$$J(M, E_j) \equiv F(M, H(M, E_j), E_j) \tag{33}$$

It is clear that $J = 0$ is seen to satisfy $F = G = 0$ in the neighborhood of (M_0, N_0, E_{j0}). Then we have

$$\left. \begin{array}{ll} J(M_0, E_{j0}) = 0 & N_0 = H(M_0, E_{j0}) \\[8pt] H_M(M_0, E_{j0}) = -\dfrac{G_M(M_0, N_0, E_{j0})}{G_N(M_0, N_0, E_{j0})} & H_{E_j}(M_0, E_{j0}) = -\dfrac{G_{E_j}(M_0, N_0, E_{j0})}{G_N(M_0, N_0, E_{j0})} \\[10pt] J_M(M_0, E_{j0}) = J_{E_j}(M_0, E_{j0}) = 0 & \end{array} \right\} \tag{34}$$

The second derivatives computed using the values of the second partial derivatives of F at (M_0, N_0, E_{j0}). It is found that at (M_0, E_{j0})

$$J_{MM} = 0 \qquad J_{E_j E_j} \neq 0 \qquad J_{ME_j} \neq 0 \tag{35}$$

$$\therefore \ J(M, E_j) = J_{ME_j}(M_0, E_{j0})(M - M_0)(E_j - E_{j0}) + \frac{1}{2}J_{E_j E_j}(M_0, E_{j0})(E_j - E_{j0})^2 + \cdots \tag{36}$$

Thus $J(M, E_j) = 0$ has two branches in the neighborhood of the point (M_0, E_{j0}). One is connected at $E_j = E_{j0}$ (37) and the other to

$$M - M_0 = - \frac{J_{E_j E_j}(M_0, E_{j0})}{2J_{ME_j}(M_0, E_{j0})} (E_j - E_{j0}) \tag{38}$$

On the second branch, the solution curve satisfies $x^0(t) = x^0(t+T)$ which corresponds to the harmonic solution obtained from equations (5). The first branch tangent to $E_j = E_{j0}$ can be investigated correctly by necessarily evaluating the third-order partial derivatives,

i.e.

$$J(M, E_j) = \frac{1}{2} J_{E_j E_j}(M_0, E_{j0}) (E_j - E_{j0})^2 + J_{ME_j}(M_0, E_{j0}) (M - M_0) (E_j - E_{j0})$$

$$+ \frac{1}{6} J_{MMM}(M_0, E_{j0}) (M - M_0)^3 + \dots \tag{39}$$

In the neighborhood of the point (M_0, E_{j0}), $J = 0$ becomes

$$E_j - E_{j0} \doteqdot - \frac{J_{MMM}(M_0, E_{j0})}{6J_{ME_j}(M_0, E_{j0})} (M - M_0)^2 \tag{40}$$

The first branch becomes the solution of period $2T$ existing only on one side $E_j = E_{j0}$.

(a) $\alpha \neq 0, n=0, j=1$ (b) $\alpha \neq 0, n=0, j=2$ (c) $\alpha = 0, n=0, j=1$

Fig. 4   Branching phenomena of solutions of order $\frac{2n+1}{2}$ ($n=0, 1, 2, \dots$) from harmonic solutions in M-E$_j$ plane in case $m=2$

(a) $\alpha \neq 0, n=0, j=1$ (b) $\alpha \neq 0, n=1, j=1$ (c) $\alpha = 0, n=0, j=1$
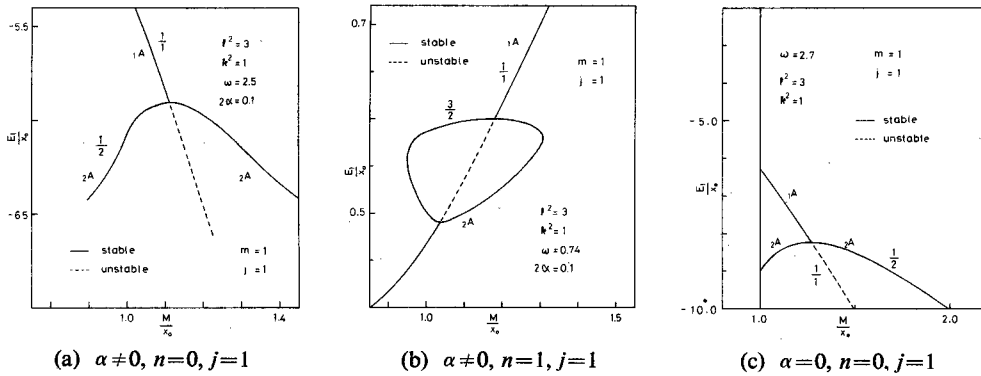

Fig. 5   Branching phenomena of solutions of order $\frac{2n+1}{2}$ ($n=0, 1, 2, \dots$) from harmonic solutions in M-E$_j$ plane in case $m=1$

(Although it is difficult to determine the sign of $J_{MMM}(M_0, E_{j0})$, in general we take $J_{MMM}(M_0, E_{j0}) \neq 0$.)

The qualitative analysis has been given above. Numerical results in the branching point neighborhood using the periodicity conditions from equations (5) are shown in Fig. 4 (a), (b), $(\alpha \neq 0)$, (c) $(\alpha = 0)$ in case $m = 2$, and Fig. 5 (a), (b), $(\alpha \neq 0)$, (c) $(\alpha = 0)$ in case $m = 1$ and are very much in agreement with analysis given above.

4.1.2 N-E_j Plane Analysis

Since $G_M \neq 0$, the equation $G(M, N, E_j) = 0$ can be solved for M as a function of N and E_j near (N_0, E_{j0}). For M the solution can be given as $M = H(N, E_j)$. Then we define the function

$$J(N, E_j) \equiv F(H(N, E_j), N, E_j) \tag{41}$$

In the same manner as in section 4.1.1 we have

$$E_j - E_{j0} = 0 \tag{42}$$

$$J_{NE_j}(N_0, E_{j0}) (N - N_0) + \frac{1}{2} J_{E_j E_j}(N_0, E_{j0}) (E_j - E_{j0}) = 0 \tag{43}$$

(a) $\alpha \neq 0, n = 0, j = 1$ (b) $\alpha \neq 0, n = 0, j = 2$

Fig. 6 Branching phenomena of solutions of order $\dfrac{2n+1}{2}$ $(n = 0, 1, 2, \ldots)$ from harmonic solutions in N-Ej plane in case $m = 2$

(a) $\alpha \neq 0, n = 0, j = 1$ (b) $\alpha \neq 0, n = 1, j = 1$
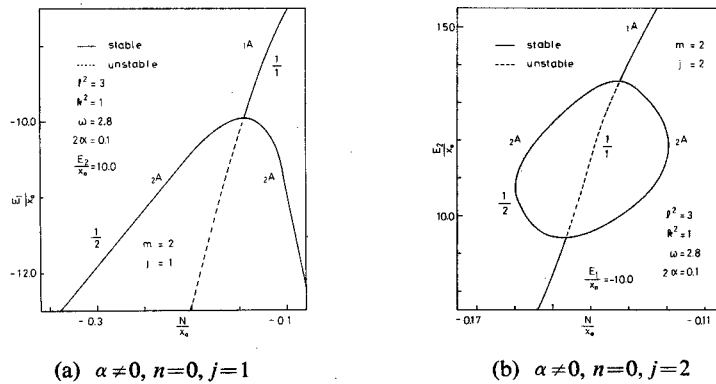

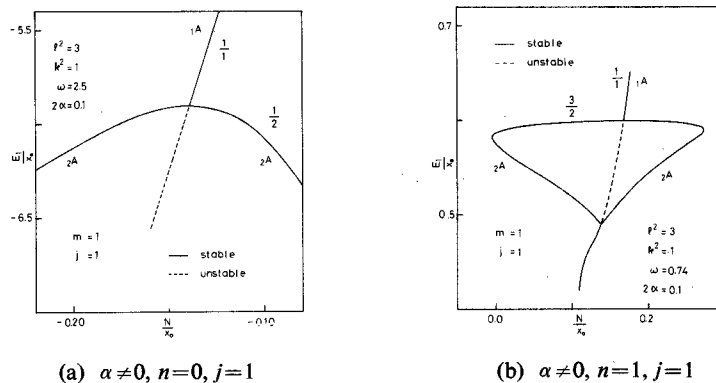

Fig. 7 Branching phenomena of solutions of order $\dfrac{2n+1}{2}$ $(n = 0, 1, 2, \ldots)$ from harmonic solutions in N-Ej plane in case $m = 1$

The first branch tangent to $E_j = E_{j0}$ means the solution of period $2T$ and further investigation gives

$$E_j - E_{j0} \doteqdot - \frac{J_{NNN}(N_0, E_{j0})}{6 J_{NE_j}(N_0, E_{j0})} (N - N_0)^2 \qquad (44)$$

The second branch is the fundamental solution obtained from equations (5). Numerical results are shown in Fig. 6 (a), (b) in case $m=2$ and Fig. 7 (a), (b) when $m=1$ and give the exact explanation of qualitative analysis.

4.1.3 *M-N* Plane Analysis

Similar investigations as to $(M-N)$ plane can be used in connection with the other sections $(M-E_j)$ and $(N-E_j)$ of the three-dimensional space of parameters. We define the function

$$J(M, N) \equiv F(M, N, H(M, N)) \qquad (45)$$

where $E_j = H(M, N)$ is the solution of equation $G(M, N, E_j) = 0$ in the neighborhood (M_0, N_0, E_{j0}), just as in 4.1.1.

(a) $\alpha \neq 0, n=0, j=1$ (b) $\alpha \neq 0, n=0, j=2$

Fig. 8 Branching phenomena of solutions of order $\frac{2n+1}{2}$ $(n=0, 1, 2, ...)$ from harmonic solutions in M-N plane in case $m=2$

(a) $\alpha \neq 0, n=0, j=1$ (b) $\alpha \neq 0, n=1, j=1$

Fig. 9 Branching phenomena of solutions of order $\frac{2n+1}{2}$ $(n=0, 1, 2, ...)$ from harmonic solutions in M-N plane in case $m=1$

After long and tedious calculations, we have two branches;

$$J_{MM}(M_0, N_0)(M-M_0)+(J_{NN}(M_0, N_0)+\sqrt{\Delta})(N-N_0)=0 \\ J_{MM}(M_0, N_0)(M-M_0)+(J_{NN}(M_0, N_0)-\sqrt{\Delta})(N-N_0)=0 \quad\Big\} \quad (46)$$

where

$$\Delta=J_{MN}^2(M_0, N_0)-J_{MM}(M_0, N_0)J_{NN}(M_0, N_0)>0 \qquad (47)$$

Numerical results are shown in Fig. 8 (a), (b) $(m=2)$ and Fig. 9 (a), (b) $(m=1)$.

4.2 Situation (II) $\rho=1$ (n=1)

When the equation (21) is satisfied, let the point satisfying equations (5) be denoted by (M_0, N_0, E_{j0}) and then we have

$$F(M_0, N_0, E_j)=G(M_0, N_0, E_{j0})=0 \qquad (48)$$

$$\begin{aligned} F_M(M_0, N_0, E_{j0})&=\varphi(T)-1 \\ F_N(M_0, N_0, E_{j0})&=\psi(T) \\ F_{E_j}(M_0, N_0, E_{j0})&=x_{E_j}(T) \\ G_M(M_0, N_0, E_{j0})&=\dot\varphi(T) \\ G_N(M_0, N_0, E_{j0})&=\dot\psi(T)-1 \\ G_{E_j}(M_0, N_0, E_{j0})&=\dot x_{E_j}(T) \end{aligned} \quad\Bigg\} \quad (49)$$

In the denominators of equation (25) we say in this case

$$\begin{aligned} F_N\cdot G_{E_j}-F_{E_j}\cdot G_N&\neq 0 \\ F_{E_j}\cdot G_M-F_M\cdot G_{E_j}&\neq 0 \\ F_M\cdot G_N-F_N\cdot G_M&=0 \end{aligned} \quad\Bigg\} \quad (50)$$
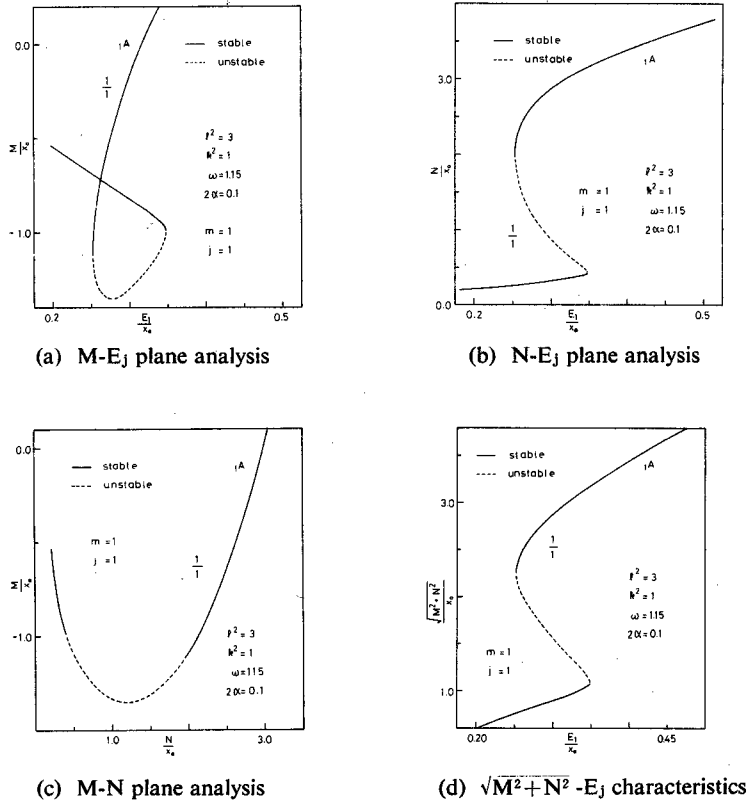

This indicates that the point (M_0, N_0, E_{j0}) is not a geometric singularity of the locus $F=G=0$. In a similar manner we have

$$\begin{aligned} E_j&=E_{j0} \quad \text{and} \\ M&-M_0+C(N-N_0)=0 \end{aligned} \quad\Big\} \quad (51)$$

where

$$C=\frac{F_N\cdot G_{E_j}-F_{E_j}\cdot G_N}{F_{E_j}\cdot G_M-F_M\cdot G_{E_j}}\Bigg|(M_0, N_0, E_{j0}) \qquad (52)$$

If we vary E_j as to increase through E_{j0} there will be two periodic solutions for E_j immediately less than E_{j0} and none for E_j immediately greater than E_{j0} if E_j is maximum at the (M_0, N_0, E_{j0}) point. As E_j increases through E_{j0} the two solutions coalesce and disappear. If E_j has a minimum at the situation (II) point, there are two solutions for E_j immediately greater than E_{j0} and none for E_j immediately less than E_{j0}, the two solutions coalescing and disappearing as E_j decreases through E_{j0}. When there are two solutions, one is stable and the other is unstable. The branching which occur at a situation (II) point is thus the well known jump phenomenon for which a stable periodic solution coalesces with an unstable solution and disappears. Numerical results are shown in Fig. 10 (a)–(d) $(m=1)$.

5. Conclusions

In the previous sections, analyses of the phenomena for the simplest piecewise linear system with unsymmetrical restoring force are present when the excitation is a sum of several harmonics in the damping case, in the same manner as in a single harmonic excitation.

These are given as follows:

(i)   For the piecewise linear system, the periodicity conditions are clarified, just as in no damping.

(ii)   For the piecewise linear system, the condition that the solutions of the first variational equation become periodic solutions are given in two types (cf. four types in no damping).

(iii)   The branching behavior of $(2n+1)/2$-harmonics ($n=0, 1, 2, 3, ...$) is the same as that of dissipationless systems.

(iv)   As to the jump phenomena the same results are given as that of system without damping.

The future work includes investigation on the difference of the analysis 1/4-fraction subharmonics between the dissipative and dissipationless systems.   The next report will deal with the bifurcation of the solutions of period 4T from the 2T-periodic

solutions of equation (1).

　　Finally, it is noted that numerical calculations were performed by using ACOS-700 at the computer center, University of Osaka Prefecture.
